Submission due date 28/10/26

(Submit by email & share google folder link for all files)

Simulate for visual demonstration of the emergence of 2d diffraction pattern in the far field for a laser illuminated object of the following type.

The vertical and horizontal lines are slits (open) of width $a = 5\mu m$ and slit seperation is $8\mu m$. Your demo module must have controls for varying the slit size, seperation along the 2 axes, the laser beam size and angle of the object in the xy plane with respect to all of which live changes in the diffractin pattern can be visualized. You can use either python or matlab.
